Description

NOVEL ACETOACETYL-CoA REDUCTASE AND PROCESS FOR PRODUCING

OPTICALLY ACTIVE ALCOHOL

Technical Field

[0001]

The present invention relates to a novel useful acetoacetyl-CoA reductase. The present invention also relates to a process for producing optically active alcohols, inter alia, a (R)-3-hydroxypentanenitrile, optically active 3-hydroxybutanoic esters, and optically active 1-phenylethanol derivatives, using the above-described enzyme or a known acetoacetyl-CoA reductase. Optically active alcohols such as a (R)-3-hydroxypentanenitrile, optically active 3-hydroxybutanoic esters, and optically active 1-phenylethanol derivatives are compounds useful as raw materials or intermediates for synthesizing various pharmaceuticals, pesticides, and the like.

Background Art

[0002]

Optically active 3-hydroxypentanenitriles, particularly a (R)-3-hydroxypentanenitrile, are highly useful as production raw materials or synthetic intermediates for various pharmaceuticals, pesticides, and the like. Thus, there has been strong need for the

development of an industrially practicable process for producing the (R)-3-hydroxypentanenitrile with high optical purity in good yield.

[0 0 0 3]

As a process for producing a (R)-3-hydroxypentanenitrile has been heretofore known a process which involves asymmetrically hydrolyzing a racemic 3-acetoxypentanenitrile using *Pseudomonas cepacia* lipase to subject to optical resolution into the (R)-3-hydroxypentanenitrile and a (S)-3-acetoxypentanenitrile (See Journal of Organic Chemistry, 62, 9165 (1997)). This process provides the (R)-3-hydroxypentanenitrile having an optical purity of 90%e.e., but is not an economical production process because it uses the enzyme at an amount of as large as one-half the weight of the substrate and has a yield of as low as 29%.

[0 0 0 4]

In addition, the above document describes that a thiocrown ether (1,4,8,11-tetrathiacyclotetradecane) may be added in the above-mentioned asymmetric hydrolysis reaction to provide a (R)-3-hydroxypentanenitrile having an optical purity of 99%e.e. or more in a yield of 49%. However, this process is not suitable for industrial practice from the viewpoints of cost and safety because the amount of the thiocrown ether necessary for the reaction is as extremely large as one-tenth the weight of the substrate. Further, for the technique in this document

the reaction products the (R)-3-hydroxypentanenitrile and a (S)-3-acetoxypentanenitrile have been separated using silica gel column chromatography, but this separation process is also impractical because of its complexity and not advantageous to adopt industrially.

[0005]

Under these circumstances, the present inventors invented a process for producing an optically active 3-hydroxypentanenitrile by subjecting a 3-ketopentanenitrile to asymmetric reduction using an enzyme, and filed an application earlier (See WO03/031636). This process can provide, in an extremely simple and easy manner, a (R)-3-hydroxypentanenitrile having high optical purity (94.8%e.e.), but there has remained room for improvement therein to obtain the desired compound with higher optical purity.

[0006]

The optically active 3-hydroxybutanoic esters, particularly an (R)-3-hydroxybutanoic ester, are also highly useful as production raw materials or synthetic intermediates for various pharmaceuticals, pesticides, and the like.

Processes for producing a (R)-3-hydroxybutanoic ester include production by the asymmetric reduction of an acetoacetic ester using a biocatalyst. For example, there are known a process using baker's yeast (see Enzyme and Microbial Technology, 31, 656 (2002)), a process using a

microorganism such as *Geotrichum candidum* or *Aspergillus niger* (see Journal of the Chemical Society, Chemical Communication, 7, 461 (1984)), and a process using glycerol dehydrogenase derived from *Geotrichum candidum* (see Tetrahedron Lett., 29, 2453 (1988)). However, these processes are practically not sufficient in terms of substrate charge concentration therefor and the ratio of conversion of substrate into product, and a more efficient synthesis process has been looked forward to.

[0 0 0 7]

The optically active 1-phenylethanol derivative is also highly useful as production raw material or synthetic intermediate for various pharmaceuticals, pesticides, and the like.

As a process for producing the optically active 1-phenylethanol derivative by enzymatic asymmetric reduction is disclosed a process which involves allowing a microorganism belonging to the genus *Ashbya* or the genus *Ogataea* or a treated product thereof to act on a 2-halo-1-(substituted phenyl)ethanone to provide an optically active 2-halo-1-(substituted phenyl)ethanol (see WO92/01804, Japanese Patent Laid-Open No. 11-215995, and WO03/00911). In addition, a similar process using recombinant *Escherichia coli* into which the gene of a phenylacetaldehyde reductase derived from *Corynebacterium* sp. ST-10 has been introduced is disclosed (Eur. J. Biochem., 269, 2394 (2002)). However, each of these

processes is low in the substrate charge concentration and the ratio of conversion of substrate into product, and there has been therefore need for a more efficient synthesis process.

[0 0 0 8]

On the other hand, enzymes reducing acetoacetyl-CoA (acetoacetyl-CoA reductases) using NADH or NADPH as a coenzyme were isolated from various microorganisms and their properties have been reported (see FEMS Microbiol. Lett., 52, 259-264 (1988) and J. Microbiol. Biotechnol., 6, 425-431 (1996)); however, it has not been reported that the acetoacetyl-CoA reductase is allowed to act on a 3-ketopentanenitrile, an acetoacetic ester or a 1-phenylethanone derivative to produce a corresponding optically active alcohol.

[0 0 0 9]

Disclosure of the Invention

Problems to be Solved by the Invention

[0 0 1 0]

An object of the present invention is to provide a novel acetoacetyl-CoA reductase highly useful for the production of optically active alcohols, inter alia, a (R)-3-hydroxypentanenitrile. A further object of the present invention is to provide an efficient process for producing optically active alcohols, inter alia, the (R)-

3-hydroxypentanenitrile, (R)-3-hydroxybutanoic esters, and optically active 1-phenylethanol derivatives.

Means for Solving the Problems

【0011】

As the result of intensive studies, the present inventors have found that an acetoacetyl-CoA reductase surprisingly can asymmetrically reduce a 3-ketopentanenitrile, acetoacetic esters, and 1-phenylethanone derivatives to produce a (R)-3-hydroxypentanenitrile, (R)-3-hydroxybutanoic esters, and optically active 1-phenylethanol derivatives, respectively.

Also, the present inventors have found and successfully isolated a novel acetoacetyl-CoA reductase, which has not been previously reported, having the activity of asymmetrically reducing a 3-ketopentanenitrile to produce a (R)-3-hydroxypentanenitrile having an optical purity of 99%e.e. or more. In addition, the present inventors have isolated a DNA encoding the enzyme and also successfully created a recombinant vector and a transformant expressing a large amount of the enzyme, thereby accomplishing the present invention.

【0012】

Thus, the present invention relates to a novel acetoacetyl-CoA reductase acting on a 3-ketopentanenitrile using NADPH or NADH as a coenzyme to produce a (R)-3-hydroxypentanenitrile having an optical purity of 99%e.e.

or more. The present invention also relates to a DNA encoding the acetoacetyl-CoA reductase, a recombinant vector containing the DNA, and a transformant producing the acetoacetyl-CoA reductase in a large quantity.

[0 0 1 3]

In addition, the invention relates to a practical process for producing a (R)-3-hydroxypentanenitrile having an optical purity of 99%e.e. or more, using the transformant.

Further, the invention relates to a practical process for producing useful optically active alcohols such as a (R)-3-hydroxypentanenitrile, (R)-3-hydroxybutanoic esters, and optically active 1-phenylethanol derivatives, using the acetoacetyl-CoA reductase.

[0 0 1 4]

The present invention is described below in detail.

As used herein, "acetoacetyl-CoA reductase" includes all of the enzymes having the ability to reduce acetoacetyl-CoA (acetoacetyl-CoA reducing activity).

The acetoacetyl-CoA reducing activity may be determined, for example, by the following method.

The reaction of a reaction solution containing 0.25 mM acetoacetyl-CoA, 0.25 mM NADPH or NADH, and the enzyme in 100 mM phosphate buffer (pH 6.5) may be effected at 30°C to determine the reducing activity by a decrease in absorbance at a wavelength of 340 nm with NADPH or NADH consumption.

【0015】

As used in the invention, a 3-ketopentanenitrile can
be synthesized, for example, by a method described in
WO94/21617. As a 3-ketopentanenitrile, 3-
ketopentanenitrile alkali metal salts represented by
following formula (9):

【0016】

$$\left[\begin{array}{c} \text{O} \\ \diagdown\diagup\diagdown\diagup\diagdown \text{CN} \end{array} \right]^{-} \text{M}^{+} \qquad (9)$$
【0017】

wherein M represents an alkali metal, such as, for example,
a 3-ketopentanenitrile sodium salt, which can be obtained
by a method described in WO03/031636, may be also used.

【0018】

The novel acetoacetyl-CoA reductase which is one
embodiment of the invention is first described in detail.

Examples of the acetoacetyl-CoA reductase of the
invention include an acetoacetyl-CoA reductase having
physicochemical properties shown in following (1) and (2)
in which:

(1) the reductase acts, using NADPH or NADH as a
coenzyme, on a 3-ketopentanenitrile represented by
following formula (1):

【0 0 1 9】

 (1)
【0 0 2 0】

to produce a (R)-3-hydroxypentanenitrile represented by following formula (2):

【0 0 2 1】

 (2)

【0 0 2 2】

having an optical purity of 99%e.e. or more; and

(2) the reductase has a molecular weight of about 85,500 as determined by gel filtration analysis and about 26,000 as determined by SDS-polyacrylamide electrophoresis analysis.

【0 0 2 3】

The optical purity, the molecular weight by gel filtration analysis, and the molecular weight by SDS-polyacrylamide electrophoresis analysis may be determined as stated in Examples to be described.

【0 0 2 4】

Preferably, the acetoacetyl-CoA reductase further has physicochemical properties shown in following (3) to (5) in which:

(3) the reductase has an optimum temperature of 27 to 33°C;

(4) the reductase has an optimum pH of 5.5 to 6.5; and

(5) the reductase is inhibited by p-chloromercuribenzoic acid, copper sulfate, silver nitrate, or mercury chloride as an inhibitor.

[0025]

Further examples of the acetoacetyl-CoA reductase of the invention can include (a) a polypeptide consisting of the amino acid sequence represented by SEQ ID NO: 1 of the Sequence Listing or (b) a polypeptide which consists of the amino acid sequence resulting from addition, deletion or substitution of one or more amino acid residues in the amino acid sequence represented by SEQ ID NO: 1 of the Sequence Listing and has the activity of acting on a 3-ketopentanenitrile to produce a (R)-3-hydroxypentanenitrile having an optical purity of 99%e.e. or more.

[0026]

The polypeptide which consists of the amino acid sequence resulting from addition, deletion or substitution of one or more amino acid residues in the amino acid sequence represented by SEQ ID NO: 1 of the Sequence Listing can be prepared according to a well-known method as described e.g. in Current Protocols in Molecular Biology (John Wiley and Sons, Inc., 1989) and falls within

the acetoacetyl-CoA reductase of the invention in so far as it has the activity of generating a (R)-3-hydroxypentanenitrile having an optical purity of 99%e.e. or more. In addition, since amino acid mutation may occur in nature, not only a polypeptide whose amino acid(s) has been artificially mutated but also a polypeptide whose amino acid(s) has been mutated in nature falls within the acetoacetyl-CoA reductase of the invention in so far as it has the activity of acting on a 3-ketopentanenitrile to produce the (R)-3-hydroxypentanenitrile having an optical purity of 99%e.e. or more.

[0027]

Here, "the activity of acting on a 3-ketopentanenitrile to produce a (R)-3-hydroxypentanenitrile having an optical purity of 99%e.e. or more" may be confirmed under the following reaction and measurement conditions.

To a test tube in which 5 mg of a 3-ketopentanenitrile, 50 mg of NADPH, and 50 µl of 1 M phosphate buffer (pH 6.5) have been preliminarily placed is added 450 µl of a solution of the enzyme (or a cell-free extract), followed by shaking overnight at 30°C. The reaction solution is extracted with 1 ml of ethyl acetate, followed by determining the optical purity of the generated 3-hydroxypentanenitrile using capillary gas chromatography.

【0028】

Capillary gas chromatography analysis conditions

Column: Chiradex G-TA (20 m × 0.25 mm) (from ASTEC Ltd.), Detection: FID

Column temperature: 120°C

Injection temperature: 200°C

Detection temperature: 200°C

Carrier gas: helium (100 kPa)

Split ratio: 100/1

Elution time: 4.37 minutes for a (R)-3-hydroxypentanenitrile, 5.17 minutes for a (S)-3-hydroxypentanenitrile.

【0029】

The acetoacetyl-CoA reductase of the invention can be found from microorganisms, animals, or plants having the ability to convert a 3-ketopentanenitrile into a (R)-3-hydroxypentanenitrile. Methods for searching the acetoacetyl-CoA reductase of the invention include, for example, a method as described in WO03/031636.

【0030】

For example, the search could be carried out from yeast as described below. In a test tube are placed 5 ml of a liquid culture medium (pH 7) consisting of 40 g of glucose, 3 g of yeast extract, 6.5 g of diammonium hydrogenphosphate, 1 g of potassium dihydrogenphosphate, 0.8 g of magnesium sulfate 7-hydrate, 60 mg of zinc sulfate 7-hydrate, 90 mg of iron sulfate 7-hydrate, 5 mg

of copper sulfate 5-hydrate, 10 mg of manganese sulfate 4-hydrate, and 100 mg of sodium chloride (each per L) before sterilization, which is then inoculated with yeast, followed by shake culture at 30°C for 2 to 3 days. Subsequently, microbial cells are collected using centrifugation and suspended in 1 to 5 ml of a phosphate buffer containing 2 to 10% by weight of glucose, which is then added to a test tube in which 2.5 to 25 mg of a 3-ketopentanenitrile has been preliminarily placed, followed by shaking at 30°C for 2 to 3 days. This reaction may be conducted after disrupting the yeast. Also, NAD^+ and/or $NADP^+$ and glucose dehydrogenase and glucose or formate dehydrogenase and formic acid may be added. After conversion reaction, extraction could be carried out using an appropriate organic solvent, followed by analyzing the generated 3-hydroxypentanenitrile using e.g. capillary gas chromatography.

[0 0 3 1]

Origins of the acetoacetyl-CoA reductase of the invention can include, for example, a bacterium belonging to the genus *Achromobacter*, which is preferably *Achromobacter xylosoxidans* subsp. *denitrificans*, more preferably *Achromobacter xylosoxidans* subsp. *denitrificans* IFO15125 strain.

[0 0 3 2]

A process for obtaining the acetoacetyl-CoA reductase of the invention from microorganisms having the ability to

asymmetrically reduce a 3-ketopentanenitrile to produce a
(R)-3-hydroxypentanenitrile is described below, but the
invention is not limited thereto.

【0033】

A microorganism is cultured in an appropriate medium,
and microbial cells are separated by centrifugation from
the culture solution, followed by suspending the microbial
cells in an appropriate buffer solution. The microbial
cells can be disrupted or lysed using a physical means
such as glass bead, a biochemical means such as enzyme, or
the like, followed by further removing solid matter in the
solution e.g. by centrifugation to provide a solution
containing the enzyme of the invention. Alternatively, the
enzyme solution can be directly obtained without
separating the microbial cells from the culture solution,
using a similar method to that mentioned above.

【0034】

Further, purification techniques generally used by
those skilled in the art, for example, ammonium sulfate
precipitation, dialysis, and chromatography, may be also
conducted alone or in combination. Examples of
chromatography include hydrophobic interaction
chromatography, ion exchange chromatography, and gel
filtration chromatography. These can provide an enzyme
solution containing no unnecessary proteins and thus
having higher purity.

【0035】

The DNA encoding the acetoacetyl-CoA reductase of the
invention may be any DNA encoding the above-described
acetoacetyl-CoA reductase. For example, the DNA may be a
DNA consisting of the base sequence represented by SEQ ID
NO: 2 of the Sequence Listing.

【0036】

A process for obtaining a DNA encoding the enzyme of
the invention is described below, but the present
invention is not limited thereto.

The purified enzyme is digested with endopeptidase
before the cleaved fragments are purified with reversed-
phase HPLC, followed by determining some of the partial
amino acid sequences using a protein sequencer. Then, PCR
(Polymerase Chain Reaction) primers are synthesized on the
basis of the resultant partial amino acid sequences.
Subsequently, from a microorganism representing the origin
of the DNA, a chromosomal DNA of the microorganism is
prepared using a conventional DNA isolation method, for
example, the Hereford method (Cell, 18, 1261 (1979)). This
chromosomal DNA is used as template to carry out PCR
employing the above-mentioned PCR primers to amplify a
portion (core sequence) of the DNA encoding the
polypeptide, followed by determining the base sequence.
The base sequence determination can be accomplished by the
dideoxy chain termination method or the like, using, for e

x a m p l e , an ABI 373A DNA Sequencer (from Applied

Biosystems).

[0 0 3 7]

In order to reveal the base sequence of the

peripheral region of the core sequence, the chromosomal

DNA of the microorganism is then digested using a

restriction enzyme whose recognition sequence is not

present in the core sequence, followed by subjecting the

generated DNA fragment to self cyclization using T4 ligase

to prepare template DNA for inverse PCR (Nucleic Acids Res.

16, 8186 (1988)). On the basis of the core sequence,

primers providing initiations of DNA synthesis toward the

outside of the core sequence are then synthesized, and

used to amplify the peripheral region of the core sequence

by the inverse PCR. The base sequence of the DNA thus

obtained can be revealed to determine the DNA sequence of

the whole coding region of the acetoacetyl-CoA reductase

of interest.

[0 0 3 8]

The vector used to introduce the DNA encoding the

acetoacetyl-CoA reductase of the invention into a host

microorganism and express the DNA in the host

microorganism having it introduced may be any vector which

enables the expression of the polypeptide gene in an

appropriate host microorganism. Such vectors include, for

example, a plasmid vector, a phage vector, and a cosmid

vector. A shuttle vector, which enables genetic exchange with other host strains, can be also used.

These vectors have a control element including an operatively linked promoter (lacUV5 promotor, trp promoter, trc promoter, tac promoter, lpp promoter, tufB promoter, recA promoter, pL promoter or the like), and can be suitably used as expression vectors containing an expression unit operatively liked to the DNA of the invention. For example, pUCNT (WO94/03613) and the like can be suitably used.

[0 0 3 9]

As used herein, the term "control element" refers to a base sequence having a functional promoter and any related transcription element (for example, an enhancer, a CCAAT box, a TATA box, and a SPI site).

As used herein, the term "operatively linked" refers to the linkage of DNA with various regulatory elements such as promoter and enhancer regulating the expression thereof in a state enabling them to operate in a host cell so as to express the gene. It is well known to those skilled in the art that the type and kind of the control element will vary depending on a host.

[0 0 4 0]

Host cells into which a vector containing the DNA of the invention is introduced include bacteria, yeast, filamentous fungi, plant cells, and animal cells, and bacteria, particularly *Escherichia coli*, are preferable

from the view point of ease of introduction and expression efficiency.

The DNA of the invention may be introduced into the host cell by the law of the art. When *Escherichia coli* is used as a host cell, the DNA of the invention may be introduced, for example, by the calcium chloride method.

[0 0 4 1]

When a 3-ketopentanenitrile is asymmetrically reduced using the acetoacetyl-CoA reductase of the invention or a transformant having the ability to produce the reductase to synthesize a (R)-3-hydroxypentanenitrile having an optical purity of 99%e.e. or more, NADPH or NADH is required as a coenzyme. Although the required amount of NADPH or NADH can be added to the reaction system to accomplish the reaction, the reaction may be performed using an enzyme having the ability to convert the oxidized form of the coenzyme ($NADP^+$ or NAD^+) into the reduced form (NADPH or NADH) (hereinafter referred to as coenzyme-regenerating ability) together with the substrate thereof, that is, combining the coenzyme-regenerating system with the enzyme of the invention, to drastically reduce the used amount of the expensive coenzyme.

[0 0 4 2]

The enzyme having the coenzyme-regenerating ability may use hydrogenase, formate dehydrogenase, alcohol dehydrogenase, glucose-6-phosphate dehydrogenase, glucose dehydrogenase, or the like. Preferably, glucose

dehydrogenase and formate dehydrogenase are used; glucose dehydrogenase is particularly preferable.

Such reaction can be also performed by adding the coenzyme-regenerating system into the asymmetrical reduction reaction system, but, when a transformant obtained by transformation employing both of the DNA encoding the enzyme of the invention and the DNA encoding glucose dehydrogenase is used as catalyst, the reaction may be efficiently conducted without adding, into the reaction system, the separately prepared enzyme having the coenzyme-regenerating ability.

[0043]

Such a transformant is obtained by incorporating the DNA encoding the acetoacetyl-CoA reductase of the invention and the DNA encoding glucose dehydrogenase into a single vector and introducing it into a host cell, or is also obtained by incorporating these two kinds of DNA into an incompatible group of two different vectors, respectively and introducing them into an identical host cell.

[0044]

In this respect, the recombinant vector of the invention contains the DNA encoding the above-described acetoacetyl-CoA reductase or the DNA consisting of the base sequence represented by SEQ ID NO: 2 of the Sequence Listing, as above mentioned. Preferable examples of the

vector include a recombinant vector represented by pNTAX in Figure 2 to be described.

Examples of the recombinant vector also include that further containing the DNA encoding the above-described glucose dehydrogenase. In this respect, the glucose dehydrogenase is preferably that derived from *Bacillus megaterium*.

【0 0 4 5】

The transformant of the invention is obtained by transforming a host cell using the above-described recombinant vector.

The transformant is preferably obtained by transforming a host cell using a first recombinant vector containing the DNA encoding the above-described acetoacetyl-CoA reductase or the DNA consisting of the base sequence represented by SEQ ID NO: 2 of the Sequence Listing, and a second recombinant vector containing the DNA encoding glucose dehydrogenase.

More preferable transformants include a transformant wherein the first recombinant vector is the above-described pNTAX and the above-described glucose dehydrogenase is derived from *Bacillus megaterium*, and a transformant wherein the first recombinant vector is the pNTAX and the second recombinant vector is a recombinant vector represented by pSTVG in Figure 2 to be described.

In this respect, the host cell is preferably *Escherichia coli*.

【0046】

Specific examples of the transformant of the invention include a recombinant *Escherichia coli, E. coli* HB101 (pNTAX) (accession Number: FERM BP-10126, the original local deposit dated October 23, 2003has been transferred to the international deposit under the Budapest Treaty) and a recombinant *Escherichia coli, E. coli* HB101 (pNTAX, pSTVG) (accession number: FERM P-19567, deposit date: October 23, 2003), which have been deposited with International Patent Organism Depositary, National Institute of Advanced Industrial Science and Technology located at Central, 6, 1-1, Higashi 1-chome, Tsukuba-shi, Ibaraki-ken, Japan.

【0047】

The process for producing a (R)-3-hydroxypentanenitrile by asymmetrically reducing a 3-ketopentanenitrile using the acetoacetyl-CoA reductase is then described in detail.

【0048】

The acetoacetyl-CoA reductase used in the process may be employed without regard to the origin thereof, and may be that derived from an animal or a plant as well as a microorganism.

【0049】

Examples thereof include known acetoacetyl-CoA reductases such as those derived from *Acinetobacter* sp. RA3849 (J. Bacteriol. ,177, 4501-4507 (1995)), *Ralstonia*

eutropha (FEMS Microbiol. Lett., 52, 259-264 (1988)),

Alcaligenes latus (J. Microbiol. Biotechnol., 6, 425-431

(1996)), *Azospirillum brasilense* (J. Gen. Microbiol.,

136,1191-1196 (1990) and Mol. Gen. Genet., 231, 375-384

(1992)), *Azotobacter beijerinckii* (Biochem. J., 134, 225-

238 (1973)), *Bacillus megaterium* (Can. J. Microbiol., 41

(Suppl.1), 77-79 (1995)), *Chromatium vinosum* D strain (Eur.

J. Biochem., 209, 135-150 (1992)), *Ectothiorhodospira*

shaposhnikovii (Appl. Microbiol. Biotechnol., 40, 292-300

(1993)), *Lupinus luteus* (Plant Soil, 56, 379-390 (1980)),

Methylobacterium extorquens (FEMS Microbiol. Lett., 156,

275-279 (1997)), *Methylobacterium rhodesianum* MB126 (Arch.

Microbiol., 161, 277-280 (1994)), *Paracoccus denitrificans*

(FEMS Microbiol. Rev., 103, 257-264 (1992) and FEMS

Microbiol. Lett., 133, 85-90 (1995)), *Rhizobium lupini*

(Fiziol. Rast. (Moscow), 27, 544-550 (1980)), *Rhizobium*

meliloti 41 (Microbiology, 141, 2553-2559 (1995)),

Rhodococcus ruber NCIMB40126 (FEMS Microbiol. Rev., 103,

93-101 (1992)), *Synechococcus* sp. (Japanese Patent Laid-

Open No. 08-187085), *Syntrophomonas wolfei* subsp. *wolfei*

(Arch. Microbiol., 159, 16-20 (1993)), *Thiocapsa pfennigii*

(Appl. Microbiol. Biotechnol., 40, 292-300 (1993)), and

Zoogloea ramigera I-16-M (Arch. Microbiol., 114, 211-217

(1977) and J. Biol. Chem. 262, 97-102 (1987)).

[0050]

Also, it can be the novel acetoacetyl-CoA reductase

of the invention described above in detail, which may be,

for example, the polypeptide consisting of the amino acid sequence represented by SEQ ID NO: 1 of the Sequence Listing.

【0 0 5 1】

Further, examples of the acetoacetyl-CoA reductase used in the process include any of following (c) to (e):

(c) a polypeptide consisting of the amino acid sequence represented by SEQ ID NO: 3 of the Sequence Listing;

(d) a polypeptide consisting of the amino acid sequence resulting from addition, deletion or substitution of one or more amino acid residues in the amino acid sequence and having the activity of asymmetrically reducing a 3-ketopentanenitrile to produce a (R)-3-hydroxypentanenitrile having an optical purity of 95%e.e. or more; and

(e) a polypeptide encoded by a DNA hybridizing under stringent conditions to a DNA consisting of a base sequence complementary to the base sequence represented by SEQ ID NO: 4 of the Sequence Listing and having the activity of asymmetrically reducing a 3-ketopentanenitrile to produce a (R)-3-hydroxypentanenitrile having an optical purity of 95%e.e. or more.

【0 0 5 2】

The polypeptide is preferably derived from a microorganism belonging to the genus *Ralstonia*, particularly *Ralstonia eutoropha*.

【0 0 5 3】

A "DNA hybridizing under stringent conditions to a DNA consisting of a base sequence complementary to the base sequence represented by SEQ ID NO: 4 of the Sequence Listing" refers to a DNA obtained by using a colony hybridization, plaque hybridization, or southern hybridization method, or the like employing, as a probe, a DNA having a base sequence complementary to the whole base sequence represented by SEQ ID NO: 4 of the Sequence Listing. Specific examples include a DNA which can be identified by using a filter having a colony- or plaque-derived DNA fixed to perform hybridization at 65°C in the presence of 0.7 to 1.0 M NaCl and then washing the filter at 65°C employing an SSC solution with a 0.1 to 2 times higher concentration (an SSC solution with a one time concentration consists of 150 mM sodium chloride and 15 mM sodium citrate).

【0 0 5 4】

The hybridization may be carried out according to a method described, for example, in Molecular Cloning, A laboratory manual, second edition (Cold Spring Harbar Laboratory Press, 1989).

【0 0 5 5】

Specific examples of a hybridizable DNA include a DNA having a sequence identity to the base sequence represented by SEQ ID NO: 4 of the Sequence Listing of 60% or more, preferably 80% or more, more preferably 90% or

more, even more preferably 95% or more, which may be used for the invention in so far as the encoded polypeptide has the activity of asymmetrically reducing a 3-ketopentanenitrile to produce a (R)-3-hydroxypentanenitrile having an optical purity of 95%e.e. or more.

[0 0 5 6]

Here, "sequence identity (%)" is represented by a numerical value obtained, when two DNAs to be compared are optimally aligned, by dividing, by the total number of bases to be compared, the number of the positions at which nucleic-acid bases (e.g. A, T, C, G, U, or I) correspond between both sequences and multiplying the result by 100.

[0 0 5 7]

The above-described acetoacetyl-CoA reductase can be allowed to act on a 3-ketopentanenitrile to provide a (R)-3-hydroxypentanenitrile having an optical purity of 95%e.e. or more. Particularly, use of the above-mentioned novel acetoacetyl-CoA reductase can provide the (R)-3-hydroxypentanenitrile with an extremely high optical purity of 99%e.e. or more.

[0 0 5 8]

In this respect, when the amino acid sequence of the above-described acetoacetyl-CoA reductase or the base sequence of the DNA encoding the enzyme is already determined, the same operation as that for the novel acetoacetyl-CoA reductase of the invention described above

in detail may be conducted to prepare a transformant expressing a large amount of the enzyme, followed by performing reduction reaction using the transformant or the culture thereof.

[0 0 5 9]

Here, a recombinant vector containing the DNA consisting of the base sequence represented by SEQ ID NO: 4 of the Sequence Listing and represented as pNTRE in Figure 3 to be described may be, for example, used in addition to the above-mentioned recombinant vectors.

[0 0 6 0]

Further, the following transformants may be, for example, used in addition to the above-mentioned transformants:

a recombinant *Escherichia coli*, *E. coli* HB101 (pNTRE) (accession number: FERM P-19566, deposit date: October 23, 2003); and

a recombinant *Escherichia coli*, *E. coli* HB101 (pNTRE, pSTVG) (accession number: FERM BP-10125, the original local deposit dated October 23, 2003 has been transferred to the international deposit under the Budapest Treaty) which have been deposited with International Patent Organism Depositary, National Institute of Advanced Industrial Science and Technology located at Central 6, 1-1, Higashi 1-chome, Tsukuba-shi, Ibaraki-Ken, Japan.

【0061】

Reduction of a 3-ketopentanenitrile using a transformant expressing the acetoacetyl-CoA reductase to produce a (R)-3-hydroxypentanenitrile may be conducted as described below although it is not intended to be limited to the following process.

【0062】

To an appropriate solvent is first added a 3-ketopentanenitrile or an alkali metal salt thereof (e.g., the 3-ketopentanenitrile sodium salt) as substrate, to which a coenzyme such as $NADP^+$ and a culture product of the transformant are then added for reaction with stirring under the control of pH. This reaction is performed at a temperature of 5 to 80°C, preferably 10 to 60°C, more preferably 20 to 40°C, and, during reaction, the reaction solution is kept at a pH of 3 to 10, preferably 4 to 9, more preferably 5 to 8. The reaction may be conducted by a batch method or a continuous system.

【0063】

In the case of the batch method, the reaction substrate can be added at a charge concentration of 0.01 to 70% (w/v), preferably 0.1 to 50%, more preferably 0.5 to 30%. When the substrate 3-ketopentanenitrile is added during the reaction, the unmodified 3-ketopentanenitrile or an alkali metal salt of the 3-ketopentanenitrile (e.g., the 3-ketopentanenitrile sodium salt) may be added.

【0 0 6 4】

The transformant may be cultured in a conventional nutrient liquid medium containing a carbon source, a nitrogen source, inorganic salts, organic nutrients, and the like in so far as the microorganism proliferates. The cultivation temperature is preferably 4 to 50°C.

Here, the culture product of the transformant may be not only a culture solution or microbial cells but also lyophilized microbial cells, acetone-dried microbial cells or a disrupted product thereof, a crude enzyme solution, or a purified enzyme, and further may be an immobilized enzyme or immobilized microbial cells immobilized using a well-known means.

【0 0 6 5】

When a transformant producing both the acetoacetyl-CoA reductase and the glucose dehydrogenase is used in performing the reaction, glucose can be further added to the reaction system to drastically reduce the used amount of the coenzyme.

【0 0 6 6】

A method for obtaining a (R)-3-hydroxypentanenitrile from the reaction solution is not particularly restricted, but high purity the (R)-3-hydroxypentanenitrile is easily obtained when it is extracted directly from the reaction solution or after separating microbial cells and the like, with a solvent such as ethyl acetate, toluene, t-butylmethyl ether, hexane, or methylene chloride, followed

by dehydration and subsequent purification using silica
gel column chromatography or the like.

[0 0 6 7]

The acetoacetyl-CoA reductase may be allowed to act
on an acetoacetic ester represented by following general
formula (3):

[0 0 6 8]

$$\underset{\text{(3)}}{\overset{O}{\parallel}}$$

COOR   (3)

[0 0 6 9]

wherein R represents a lower alkyl group which is
optionally substituted or branched to efficiently produce
an (R)-3-hydroxybutanoic ester represented by following
general formula (4):

[0 0 7 0]

OH

COOR   (4)

[0 0 7 1]

wherein R is the same as defined above.

[0 0 7 2]

Preferably, the lower alkyl group R is an optionally
branched C1 to C5 alkyl group, more preferably methyl or
ethyl. In addition, the lower alkyl group is optionally
substituted, and examples of the substituent include a

halogen atom, and hydroxyl, alkoxy, nitro, and amino
groups.

【0 0 7 3】

The acetoacetyl-CoA reductase used in the reaction
may be any such reductase without regard to the origin
thereof in so far as it reduces an acetoacetic ester to an
(R)-3-hydroxybutanoic ester; the novel acetoacetyl-CoA
reductase of the invention and the above-described known
acetoacetyl-CoA reductases may be suitably used. In
addition, transformants expressing large amounts of these
enzymes, which have been bred in the same way as the
method described above, may be used. The reaction could be
conducted in the same way as that for the reduction
reaction of a 3-ketopentanenitrile described above.

【0 0 7 4】

An acetoacetyl-CoA reductase may be allowed to act on
a 1-phenylethanone derivative represented by following
formula (5):

【0 0 7 5】

(5)
【0 0 7 6】

wherein R_1 and R_2 each represent a hydrogen atom, a halogen
atom, an alkoxy group, or a nitro group, and may be the

same or different; R_3 represents a hydrogen atom, a hydroxyl group, a halogen atom, or an alkyl group which may be optionally substituted, to efficiently produce an optically active 1-phenylethanol derivative represented by following formula (6):
【0 0 7 7】

(6)

【0 0 7 8】

wherein R_1, R_2, and R_3 are each the same as defined above.

Particularly, an acetoacetyl-CoA reductase may be allowed to act on 2-chloro-1-(3'-chlorophenyl)ethanone represented by following formula (7):
【0 0 7 9】

(7)

【0 0 8 0】

to efficiently produce (R)-2-chloro-1-(3'-chlorophenyl)ethanol represented by following formula (8):

【0 0 8 1】

$$\text{(structure: 3-chlorophenyl-CH(OH)-CH}_2\text{Cl)}$$

(8)

【0 0 8 2】

【0 0 8 3】

In R_1, R_2, and R_3, the halogen atom may be, for example, a fluorine atom, a chlorine atom, a bromine atom, or an iodine atom.

In R_1 and R_2, the alkoxy group is a C1 to C3 alkoxy group, including, for example, methoxy group, ethoxy group, or propoxy group. Methoxy group is preferable.

In R_3, the alkyl group is a C1 to C8 alkyl group, including, for example, methyl group, ethyl group, propyl group, hexyl group, or octyl group. A C1 to C2 alkyl is preferable. In this respect, the alkyl group is optionally substituted, and examples of the substituent include, for example, a fluorine atom, a chlorine atom, a bromine atom, a hydroxyl group, and an amino group.

【0 0 8 4】

The acetoacetyl-CoA reductase used in the reaction may be any such reductase without regard to the origin thereof in so far as it has the activity of reducing a 1-phenylethanone derivative to an optically active 1-phenylethanol derivative, particularly the activity of

reducing 2-chloro-1-(3'-chlorophenyl)ethanone to (R)-2-chloro-1-(3'-chlorophenyl)ethanol; the novel acetoacetyl-CoA reductase of the invention and the above-described known acetoacetyl-CoA reductases may be suitably used. In addition, transformants expressing large amounts of these enzymes, which have been bred in the same way as the method described above, may be used. The reaction could be conducted in the same way as that for the reduction reaction of a 3-ketopentanenitrile described above.

Advantages of the Invention

[0085]

According to the invention, useful optically active alcohols such as a (R)-3-hydroxypentanenitrile, (R)-3-hydroxybutanoic esters, and optically active 1-phenylethanol derivatives may be produced in a simple and easy manner. Particularly for the (R)-3-hydroxypentanenitrile, non-conventional products having extremely high optical purities of 99.5%e.e. or more and, when the acetoacetyl-CoA reductase of the invention is used, 99%e.e. or more can be obtained

Best Mode for Carrying Out the Invention

[0086]

The present invention is described below in further detail with reference to Examples. However, this invention is not intended to.be limited to these Examples in any

manner. In the following description, "%" means "% by weight" unless otherwise noted.

【0087】

The production amount of 3-hydroxypentanenitrile and the optical purity thereof were determined by analysis under the following capillary gas chromatography conditions.

Capillary gas chromatography analysis conditions

Column: Chiradex G-TA (20 m × 0.25 mm) (from ASTEC Ltd.), Detection: FID

Column temperature: 120°C

Injection temperature: 200°C

Detection temperature: 200°C

Carrier gas: helium (100 kPa)

Split ratio: 100/1

Elution time: 4.37 minutes for a (R)-3-hydroxypentanenitrile, 5.17 minutes for a (S)-3-hydroxypentanenitrile.

【0088】

Example 1: Purification of a novel acetoacetyl-CoA reductase from *Achromobacter xylosoxidans* subsp. *denitrificans* IFO15125 strain

The activity of reducing a 3-ketopentanenitrile to 3-hydroxypentanenitrile was determined as follows. To a test tube in which 5 mg of a 3-ketopentanenitrile and 30 mg of NADPH had been placed were added 0.05 ml of 1 M phosphate buffer (pH 6.5) and 0.45 ml of polypeptide (enzyme)

solution, followed by shaking at 30°C for one hour. Thereto was added 1 ml of ethyl acetate, which was then thoroughly stirred, followed by centrifugation. The organic layer was analyzed under the above-described capillary gas chromatography conditions to determine the amount of 3-hydroxypentanenitrile produced. A reduction activity to produce 1 μmol of 3-hydroxypentanenitrile per minute under the conditions was defined as 1 unit. The optical purity of 3-hydroxypentanenitrile was also analyzed and determined under the capillary gas chromatography conditions.

[0089]

Into a Sakaguchi flask was dispensed 100 ml of a liquid medium consisting of 10 g of meat extract, 10 g of peptone, 5 g of yeast extract, and 3 g of sodium chloride (each per L), followed by steam sterilization at 120°C for 20 minutes. Ten flasks of the liquid medium were provided, each of which then was aseptically inoculated with one platinum loop of *Achromobacter xylosoxidans* subsp. *denitrificans* IFO15125 strain, followed by shake culture at 30°C for 40 hours. Microbial cells were collected from 500 ml of the resultant culture solution by centrifugation, and washed with 200 ml of 10 mM phosphate buffer (pH 7.0), and the wet cells were suspended in 30 ml of a 10 mM phosphate buffer to which β-mercaptoethanol was added to give a concentration of 1 mM. Then, the microbial cells were disrupted using an ultrasonic homogenizer (from

Branson), followed by removing the microbial cell residue using centrifugal separation to provide 25 ml of a cell-free extract. The extract was applied to a Toyopearl DEAE-650M (from Tosoh) column (10 ml) preliminarily equilibrated with a 20 mM phosphate buffer (pH 7.0) containing 1 mM β-mercaptoethanol to adsorb enzyme, followed by performing elution by increasing the concentration of sodium chloride stepwise (from 0 mM until 500 mM) to provide fractions having the activity of reducing a 3-ketopentanenitrile. Such active fractions were gathered, and applied to a HiLoad 16/60 Superdex 200 prep grade (from Amersham Pharmacia Biotech) column preliminarily equilibrated with a 20 mM phosphate buffer (pH 7.0) containing 1 mM β-mercaptoethanol. Further, the active fraction was applied to a 2'5'ADP Sepharose 4B (from Amersham Pharmacia Biotech) column (18 ml) preliminarily equilibrated with a 20 mM phosphate buffer (pH 7.0) containing 1 mM β-mercaptoethanol to adsorb enzyme, followed by eluting an active fraction with a linear gradient of sodium chloride (from 0 mM until 1.0 M). The above purification operation resulted in the provision of an electrophoretically almost single purified polypeptide preparation. In SDS polyacrylamide electrophoresis analysis, the molecular weight of a band was determined according to the protocol of an LMW calibration kit for SDS-electrophoresis from Amersham Bioscience. As a result, the molecular weight was

approximately 26,000. By allowing this purified enzyme to act on a 3-ketopentanenitrile in the presence of NADPH, a (R)-3-hydroxypentanenitrile having an optical purity of 99.2%e.e. was produced. This acetoacetyl-CoA reductase is hereinafter referred to as "RAX".

【0 0 9 0】

Example 2: Determining the properties of the enzyme

The enzymatic properties of the resultant RAX were examined.

(1) Action

NADPH was used as a coenzyme to allow RAX to act on a 3-ketopentanenitrile to reduce it to a (R)-3-hydroxypentanenitrile having an optical purity of 99.2%e.e. When NADH was used as a coenzyme in place of NADPH to determine the 3-ketopentanenitrile-reducing activity thereof as described in Example 1, the activity was about 15% of that for the use of NADPH as a coenzyme.

In addition, the activities of reducing acetoacetyl-CoA and ethyl 4-chloroacetoacetate were examined. A reaction solution containing 0.25 mM acetoacetyl-CoA or 10 mM ethyl 4-chloroacetoacetate, 0.25 mM NADPH, and the enzyme in a 100 mM phosphate buffer (pH 6.5) was subjected to reaction at 30°C to determine a reduction in absorbance at a wavelength of 340 nm with NADPH consumption to evaluate the activity of reducing each substrate. An enzyme activity for oxidizing 1 μmol of NADPH to $NADP^+$ per minute under the conditions was defined as 1 unit. As a

result, it was noted that RAX had the activities of reducing both acetoacetyl-CoA and ethyl 4-chrloroacetoacetate, which were about 7.6 times and about 3.2 times, respectively, the 3-ketopentanenitrile-reducing activity thereof determined as described in Example 1.

[0 0 9 1]

(2) Optimal temperature for action

To examine the optimal temperature for action of RAX, the ethyl 4-chloroacetoacetate reducing activity thereof was determined at 10 to 50°C. The activity was determined by adding 10 mM of the substrate ethyl 4-chloroacetoacetate, 0.25 mM of the coenzyme NADPH, and the enzyme to a 100 mM phosphate buffer (pH 6.5) for reaction at 10 to 50°C for 3 minutes and determining a reduction in absorbance at a wavelength of 340 nm. As a result, the optimal temperature was 27 to 33°C.

[0 0 9 2]

(3) Optimal pH for action

To examine the optimal pH for action of RAX, the ethyl 4-chloroacetoacetate reducing activity thereof was determined at a pH of 4 to 9. The enzyme activity was determined by adding 10 mM of the substrate ethyl 4-chloroacetoacetate, 0.25 mM of the coenzyme NADPH, and the enzyme to a buffer for reaction at 30°C for 3 minutes and determining a reduction in absorbance at a wavelength of 340 nm. The activity determination was performed at a pH range of 4 to 9 using a 100 mM phosphate buffer, a 100 mM

acetate buffer, or a 100 mM Tris-hydrochloride buffer. As a result, the optimal pH was 5.5 to 6.5.

【0 0 9 3】

(4) Inhibitors

The ethyl 4-chloroacetoacetate reducing activity thereof was determined under the condition of adding any of various compounds and metal salts. The activity determination was performed by adding 10 mM of the substrate ethyl 4-chloroacetoacetate, 0.25 mM of the coenzyme NADPH, the enzyme, and an inhibitor to a 100 mM phosphate buffer (pH 6.5) for reaction at 30°C for 3 minutes and determining a reduction in absorbance at a wavelength of 340 nm. The activity in the absence of inhibitor is set to 100%, and the activities in the presence of inhibitors are defined as relative activities in Table 1.

【0094】

Table 1

Inhibitor	Concentration (mM)	Relative activity
None	-	100
Iodoacetic acid	1.0	98
N-Ethylmaleimide	1.0	103
p-Chloromercuribenzoic acid	1.0	0
Phenylmethylsulfonyl fluoride	1.0	108
EDTA	1.0	83
$MgSO_4$	1.0	100
$MnCl_2$	1.0	97
$ZnSO_4$	1.0	81
$CoCl_2$	1.0	108
$CuSO_4$	1.0	0
$AgNO_3$	0.1	0
$HgCl_2$	0.01	0

【0095】

As a result, the enzyme activity was inhibited by p-chloromercuribenzoic acid, copper sulfate, silver nitrate, or mercury chloride.

(5) Molecular weight

The gel filtration chromatography analysis of the purified enzyme by Superdex 200 HR 10/30 (from Pharmacia Biotech) was carried out using, as an eluting solution, a 50 mM phosphate buffer (pH 7.0) containing 150 mM sodium chloride. As a result, the molecular weight of the enzyme calculated from the relative retention time thereof with respect to a reference protein was approximately 85,500.

【0 0 9 6】

Example 3: RAX gene cloning

The purified enzyme obtained in Example 1 was denatured in the presence of 8 M urea and then digested using an *Achromobacter*-derived lysyl endopeptidase (from Wako Pure Chemical Industries), followed by determining the amino acid sequences of the resultant peptide fragments by the Edman method.

In consideration of the DNA sequences predicted from the above amino acid sequences, primer 1 (5'-CARGGNTAYACNTTYTAYG-3': SEQ ID NO: 5) and primer 2 (5'-GCDATYTCYTCNGGNGTYCC-3': SEQ ID NO: 6) were synthesized. There was prepared 100 µl of a buffer for ExTaq containing 100 pmol each of the two kinds of primers (primers 1 and 2), 866 ng of a chromosomal DNA of *Achromobacter xylosoxidans* subsp. *denitrificans* IFO15125 strain, 10 nmol each of dNTP (deoxynucleotide triphosphate), and 2.5 U of ExTaq (from Takara Shuzo), and 30 cycles of thermal denaturation (96°C, 1 min.), annealing (50°C, 1 min.), and elongation reaction (72°C, 1 min.) were performed before cooling to 4°C, followed by identifying the amplified DNA using agarose gel electophoresis.

【0 0 9 7】

The chromosomal DNA of *Achromobacter xylosoxidans* subsp. *denitrificans* IFO15125 strain was prepared by the method for preparing a small amount of a bacterial genomic DNA as described in Bunshi Seibutsugaku Jikken (Molecular

Biology Experiments) Protocol 1 (Maruzen Co., Ltd.), p.36.
The amplified DNA was subcloned in the pT7Blue Vector
(from Novagen) and subsequently sequenced. As a result,
the amplified DNA, including the primer sequence,
consisted of 503 bases. The DNA sequence is the doubly-
underlined portion of the DNA sequence shown in Figure 1.
This sequence is hereinafter referred to as "core
sequence".

[0098]

Based on a base sequence close to the 5' end of the
core sequence, primer 3 (5'-CGTCGGCGCTCATCTTGCGGAACAG-3':
SEQ ID NO: 7) providing a complementary sequence thereto
was prepared; further, based on a base sequence close to
the 3' end thereof, primer 4 (5'-
AGGGCATCACGGTCAACACGGTGTC-3': SEQ ID NO: 8) was prepared.
To prepare a template for inverse PCR, the chromosomal DNA
of *Achromobacter xylosoxidans* subsp. *denitrificans*
IFO15125 strain was first digested using the restriction
enzyme SphI, and the digest was self-cyclized using T4DNA
ligase. There was prepared 50 μl of a buffer for ExTaq
containing 300 ng of the self-cyclized matter, 50 pmol
each of the two kinds of primers (primers 3 and 4), 10
nmol each of dNTP, and 2.5 U of ExTaq (from Takara Shuzo),
and 30 cycles of thermal denaturation (97°C, 0.5 min.),
annealing (68°C, 1 min.), and elongation reaction (72°C, 5
min.) were performed before cooling to 4°C, followed by

identifying the amplified DNA using agarose gel electophoresis.

【0 0 9 9】

The amplified DNA was subcloned in the pT7Blue Vector (from Novagen) and subsequently sequenced. From this result and the result of the core sequence, the whole base sequence of the gene encoding RAX was determined. The whole base sequence is shown in SEQ ID NO: 15 of the Sequence Listing. The whole base sequence and the deduced amino acid sequence encoded by the gene are defined in Figure 1. In Figure 1, the single underlines show the amino acid sequences determined by the Edman method in peptide fragments generated by subjecting the purified RAX to lysyl endopeptidase digestion.

【0 1 0 0】

Example 4: Preparation of a recombinant vector containing the RAX gene

To express RAX in *Escherichia coli*, a recombinant vector used for transformation was prepared. A double-stranded DNA consisting of the RAX gene in which an NdeI site was added to the initiation codon region thereof and an additional termination codon and an EcoRI site were added immediately after the termination codon thereof was first obtained as described below.

Based on the base sequence determined in Example 3, primer 5 consisting of an initiation codon region of the RAX gene to which the NdeI site was added (5'-

GTACATATGAGCGGAAAACTGGCTTACG-3': SEQ ID NO: 9) and primer 6, which had an additional termination codon and the EcoRI site added immediately after the termination codon of the RAX gene and, further, an NdeI site substituted by one base for destruction thereof, (5'-GTAGAATTCTTATCAGCCCATGTGCAGGCCGCCG-3': SEQ ID NO: 10) were synthesized. There was prepared 100 µl of a buffer for ExTaq containing 100 pmol each of the two kinds of primers (primers 5 and 6), 132 ng of a chromosomal DNA of *Achromobacter xylosoxidans* subsp. *denitrificans* IFO15125 strain, 20 nmol each of dNTP, and 2.5 U of ExTaq (from Takara Shuzo), and 30 cycles of thermal denaturation (97°C, 0.5 min.), annealing (65°C, 1 min.), and elongation reaction (72°C, 1 min.) were performed before cooling to 4°C, followed by identifying the amplified DNA using agarose gel electophoresis. This amplified fragment was digested with NdeI and EcoRI, and inserted into the NdeI and EcoRI sites downstream of the lac promoter of the plasmid pUCNT (WO94/03613) to provide a recombinant vector, pNTAX. The method for preparing pNTAX and the structure thereof are shown in Figure 2.

[0 1 0 1]

Example 5: Preparation of a recombinant vector simultaneously containing both the RAX gene and the glucose dehydrogenase

A double-stranded DNA consisting of the gene of glucose dehydrogenase (hereinafter referred to as GDH)

derived from *Bacillus megaterium* IAM1030 strain to which the Shine-Dalgarno sequence (9 nucleotides) of *Escherichia coli* 5 bases upstream of the initiation codon thereof, a EcoRI cleavage point immediately before the sequence, and an SalI cleavage point immediately after the termination codon thereof were added was obtained as described below.

【0 1 0 2】

Based on the base sequence information of the gene of GDH, primer 7, which had the Shine-Dalgarno sequence (9 nucleotides) of *Escherichia coli* added 5 bases upstream of the initiation codon of the structural gene of GDH and, further, the EcoRI cleavage point added immediately before the sequence, (5'-GCCGAATTCTAAGGAGGTTAACAATGTATAAAGATTTAGAAGG-3': SEQ ID NO: 11) and primer 8, which had the SalI site added immediately after the termination codon thereof, (5'-GCGGTCGACTTATCCGCGTCCTGCTTGG-3': SEQ ID NO: 12) were synthesized by the law of the art. Employing these two kids of primers, the plasmid pGDK1 (Eur. J. Biochem., 186, 389 (1989)) was used as a template to synthesize a double-stranded DNA by PCR. The resultant DNA fragment was digested with EcoRI and SalI, followed by inserting the digest into the EcoRI-SalI site of pNTAX constructed in Example 4 to provide a recombinant vector, pNTAXG. The method for preparing pNTAXG and the structure thereof are shown in Figure 2.

【0103】

Example 6: Preparation of a recombinant *Escherichia coli* producing RAX

The *Escherichia coli* HB101 (from Takara Shuzo) was transformed using the recombinant vector pNTAX obtained in Example 4 and the recombinant vector pNTAXG obtained in Example 5 to provide recombinant *Escherichia colis*, HB101 (pNTAX) and HB101 (pNTAXG), respectively. The recombinant *Escherichia coli* HB101 (pNTAX) (Accession number: FERM BP-10126, the original local deposit dated October 23, 2003 has been transferred to the international deposit under the Budapest Treaty) has been deposited with International Patent Organism Depositary, National Institute of Advanced Industrial Science and Technology.

【0104】

In addition, a DNA fragment of about 0.8 kb containing the GDH gene obtained by subjecting the recombinant vector pNTAXG prepared in Example 5 to double digestion using EcoRI and PstI was inserted into the EcoRI-PstI site of the plasmid pSTV28 (from Takara Shuzo) to construct a recombinant vector, pSTVG. The method for preparing pSTVG and the structure thereof are shown in Figure 2. The recombinant *Escherichia coli* HB101 (pNTAX), preliminarily made competent by the calcium chloride method, was transformed using this pSTVG to provide a recombinant *Escherichia coli*, HB101 (pNTAX, pSTVG). The recombinant *Escherichia coli* HB101 (pNTAX, pSTVG) as a

transformant thus obtained (accession number: FERM P-19567, deposit date: October 23, 2003) has been deposited with International Patent Organism Depositary, National Institute of Advanced Industrial Science and Technology.

[0 1 0 5]

Example 7: Expression of RAX and GDH in the recombinant Escherichia coli

Into a 500-ml Sakaguchi flask was dispensed 50 ml of 2×YT medium (pH 7) consisting of 1.6% (w/v) of Bacto tryptone, 1.0% (w/v) of Bacto yeast extract, and 10.5% (w/v) of NaCl, followed by steam sterilization at 120°C for 20 minutes. The recombinant Escherichia colis HB101 (pNTAX), HB101 (pNTAXG), and HB101 (pNTAX, pSTVG) obtained in Example 6, and a recombinant Escherichia coli HB101 (pUCNT), as a transformant containing only vector plasmid were each inoculated on the medium, followed by shake culture at 37°C for 18 hours. However, ampicillin was added so as to reach 120 μg/ml in culturing HB101 (pNTAX), HB101 (pNTAXG), or HB101 (pUCNT), and ampicillin and chloramphenicol were added so as to reach 120 μg/ml and 50 μg/ml, respectively in culturing HB101 (pNTAX, pSTVG). After collection, each of the bacteria was suspended in a 10 mM phosphate buffer (pH 7) and subjected to ultrasonic disruption to provide a cell-free extract. A 3-ketopentanenitrile-reducing specific activity and a GDH specific activity were determined for the cell-free extract from each recombinant Escherichia coli. The GDH

specific activity was determined by adding 0.1 M of the substrate glucose, 2 mM of the coenzyme NADP$^+$, and the enzyme to a 1M Tris hydrochloride buffer (pH 8.0) to determine an increase in absorbance at a wavelength of 340 nm at 25°C. An enzyme activity for reducing 1 μmol of NADP$^+$ to NADPH per minute under the conditions was defined as 1 unit. The results are shown in Table 2.

【0 1 0 6】

Table 2

Strain name	3-ketopentanenitrile-reducing specific activity (units/mg)	GDH specific activity (units/mg)
HB101(pUCNT)	<0.1	<0.01
HB101(pNTAX)	9.3	<0.01
HB101(pNTAXG)	4.3	195
HB101(pNTAX,pSTVG)	7.0	10

【0 1 0 7】

The recombinant *Escherichia coli* HB101 (pNTAX) showed an apparent increase in a 3-ketopentanenitrile-reducing specific activity compared to that for the recombinant *Escherichia coli* HB101 (pUCNT) as a transformant containing only vector plasmid. The recombinant *Escherichia colis* HB101 (pNTAXG) and HB101 (pNTAX, pSTVG) showed apparent increases in the 3-ketopentanenitrile-reducing specific activity and GDH specific activity compared to those for the recombinant *Escherichia coli* HB101 (pUCNT) as a transformant containing only vector plasmid.

【0108】

Example 8: Synthesis of a (R)-3-hydroxypentanenitrile from a 3-ketopentanenitrile using the recombinant *Escherichia coli* HB101 (pNTAX)

The recombinant *Escherichia coli* HB101 (pNTAX) was cultured and subjected to cell disruption as described in Example 7 to prepare a cell-free extract. To a test tube in which 5 mg of a 3-ketopentanenitrile, 50 mg of NADPH, and 50 μl of 1 M phosphate buffer (pH 6.5) were preliminarily placed was added 450 μl of the above cell-free extract, followed by shaking overnight at 30°C. Extraction was then performed twice using 1 ml of ethyl acetate, followed by determining the production amount and optical purity of the resultant 3-hydroxypentanenitrile. As a result, the production amount was 3.7 mg, and the optical purity was (R)99.2%e.e.

【0109】

Example 9: Synthesis of a (R)-3-hydroxypentanenitrile from a 3-ketopentanenitrile using the recombinant *Escherichia coli* HB101 (pNTAXG)

The recombinant *Escherichia coli* HB101 (pNTAXG) was cultured and subjected to cell disruption as described in Example 7 to prepare a cell-free extract. To 450 μl of the cell-free extract were added 50 μl of 1 M phosphate buffer (pH 6.5), 13.9 mg of glucose, 1 mg of $NADP^+$, and 5 mg of a 3-ketopentanenitrile, followed by stirring overnight at 30°C. After reaction, the production amount and optical

purity of the resultant 3-hydroxypentanenitrile were
determined. As a result, the production amount was 4.5 mg,
and the optical purity was 99.2%e.e.

[0 1 1 0]

Example 10: Synthesis of a (R)-3-hydroxypentanenitrile
from a 3-ketopentanenitrile using the recombinant
Escherichia coli HB101 (pNTAX, pSTVG)

The recombinant *Escherichia coli* HB101 (pNTAX, pSTVG)
was cultured as described in Example 7. To 20 ml of the
resultant culture solution were added 5.0 g of glucose, 3
mg of $NADP^+$, and 0.2 g of a 3-ketopentanenitrile sodium
salt, followed by stirring at 30°C while adding dropwise a
5N sodium hydroxide aqueous solution to adjust to pH 6.5.
The addition of 0.2 g of the 3-ketopentanenitrile sodium
salt was carried out 1.5, 3, 4.8, 5.7, 7, and 9 hours
after the reaction. In addition, 4 ml of the culture
solution and 3 mg of $NADP^+$ were added 9.4 hours after the
reaction. The production amount and optical purity of the
resultant 3-hydroxypentanenitrile were determined 24 hours
after the reaction. As a result, the production amount was
1.1 g, and the optical purity was 99.2%e.e.

[0 1 1 1]

Example 11: Synthesis of a (R)-3-hydroxypentanenitrile
from a 3-ketopentanenitrile using the recombinant
Escherichia coli HB101 (pNTAX, pSTVG)

The recombinant *Escherichia coli* HB101 (pNTAX, pSTVG)
was cultured as described in Example 7. In a 1-L separable

flask were placed 400 ml of the resultant culture solution, 36.3 g of glucose, 50 mg of NADP$^+$, and 3.5 g of a 3-ketopentanenitrile sodium salt, followed by adjusting pH to 6.5 before stirring at 30°C. A separately prepared 3-ketopentanenitrile aqueous solution having 18.5 g of the 3-ketopentanenitrile sodium salt dissolved in 37 ml of an ion exchanged water was added to maintain the pH of the reaction solution at 6.5. After adding the total amount of the 3-ketopentanenitrile aqueous solution, a 30% sodium hydroxide aqueous solution was added to keep the reaction solution at a pH of 6.5. After the end of reaction, the reaction solution was extracted with ethyl acetate, and the aqueous phase was further extracted with ethyl acetate. The organic phases were combined to remove the solvent under reduced pressure, followed by purification through distillation. As a result, 13.5 g of a (R)-3-hydroxypentanenitrile having an optical purity of 99.2%e.e. was obtained.

Example 12: Preparation of a recombinant vector containing the gene encoding an acetoacetyl-CoA reductase derived from *Ralstonia eutropha* ATCC17699 strain.

To express a *Ralstonia eutropha*-derived acetoacetyl-CoA reductase (hereinafter referred to as RRE) in *Escherichia coli*, a recombinant vector used for transformation was prepared. In obtaining the RRE gene, the base sequence information of the RRE gene described in

J. Biol. Chem., 264, 15293 (1989) was consulted. A double-stranded DNA consisting of the RRE gene in which an NdeI site was added to the initiation codon region thereof and an additional termination codon and an EcoRI site were added immediately after the termination codon thereof was first obtained as described below.

[0 1 1 3]

Primer 9 consisting of an initiation codon region of the RRE gene to which the NdeI site was added (5'-AAGGAGTGCATATGACTCAGCGCATTGCGTATGTG-3': SEQ ID NO: 13) and primer 10, which had an additional termination codon and the EcoRI site added immediately after the termination codon thereof and, further, an NdeI site substituted by one base for destruction thereof, (5'-GTAGAATTCTTATCAGCCCATGTGCAGGCCGCCG-3': SEQ ID NO: 14) were synthesized. There was prepared 100 μl of a buffer for ExTaq containing 100 pmol each of the two kinds of primers (primers 9 and 10), 132 ng of a chromosomal DNA of *Ralstonia eutropha* ATCC17699 strain, 20 nmol each of dNTP, and 2.5 U of ExTaq (from Takara Shuzo), and 30 cycles of thermal denaturation (97°C, 0.5 min.), annealing (65°C, 1 min.), and elongation reaction (72°C, 1 min.) were performed before cooling to 4°C, followed by identifying the amplified DNA using agarose gel electophoresis. The chromosomal DNA of *Ralstonia eutropha* ATCC17699 strain used for PCR was prepared in the same way as that for the

chromosomal DNA of *Achromobacter xylosoxidans* subsp. *denitrificans* IFO15125 strain as described in Example 3.

The above-described amplified fragment was digested with NdeI and EcoRI, and inserted into the NdeI-EcoRI site downstream of the lac promoter of the plasmid pUCNT (WO94/03613) to provide a recombinant vector, pNTRE. The method for preparing pNTRE and the structure thereof are shown in Figure 3.

[0 1 1 4]

Example 13: Preparation of a recombinant *Escherichia coli* producing RRE

An *Escherichia coli* HB101 (from Takara Shuzo) was transformed using the recombinant vector pNTRE obtained in Example 12 to provide a recombinant *Escherichia coli* HB101 (pNTRE). The recombinant *Escherichia coli* HB101 (pNTRE) as a transformant thus obtained (accession number: FERM P-19566, deposit date: October 23, 2003) has been deposited with International Patent Organism Depositary, National Institute of Advanced Industrial Science and Technology.

The recombinant *Escherichia coli* HB101 (pNTRE), preliminarily made competent by the calcium chloride method, was transformed using the recombinant vector pSTVG obtained in Example 6 to provide a recombinant *Escherichia coli* HB101 (pNTRE, pSTVG). The recombinant *Escherichia coli* HB101 (pNTRE, pSTVG) as a transformant thus obtained (accession number: FERM BP-10125, the original local deposit dated October 23, 2003 has been transferred to the

international deposit under the Budapest Treaty) has been deposited with International Patent Organism Depositary, National Institute of Advanced Industrial Science and Technology.

Example 14: Expression of RRE and GDH in a recombinant Escherichia coli

The recombinant Escherichia colis HB101 (pNTRE) and HB101 (pNTRE, pSTVG) obtained in Example 13 and the recombinant Escherichia coli HB101 (pUCNT) as a transformant containing only vector plasmid were cultured as described in Example 7, followed by preparing a cell-free extract. A 3-ketopentanenitrile-reducing specific activity and a GDH specific activity were determined for the cell-free extract from each recombinant Escherichia coli. The results are shown in Table 3.

【0 1 1 6】

Table 3

Strain name	3-Ketopentanenitrile-reducing specific activity (units/mg)	GDH specific activity (units/mg)
HB101(pUCNT)	<0.1	<0.01
HB101(pNTRE)	3.6	<0.01
HB101(pNTRE,pSTVG)	2.9	19

【0 1 1 7】

The recombinant Escherichia coli HB101 (pNTRE) showed an apparent increase in a 3-ketopentanenitrile-reducing specific activity compared to that for the recombinant Escherichia coli HB101 (pUCNT) as a transformant

Escherichia coli HB101 (pUCNT) as a transformant
containing only vector plasmid. The recombinant
Escherichia coli HB101 (pNTRE, pSTVG) showed apparent
increases in the 3-ketopentanenitrile-reducing specific
activity and GDH specific activity compared to those for
the recombinant *Escherichia coli* HB101 (pUCNT) as a
transformant containing only vector plasmid.

[0 1 1 8]

Example 15: Synthesis of a (R)-3-hydroxypentanenitrile
from a 3-ketopentanenitrile using the recombinant
Escherichia coli HB101 (pNTRE)

The recombinant *Escherichia coli* HB101 (pNTRE) was
cultured and subjected to cell disruption as described in
Example 7 to prepare a cell-free extract. To a test tube
in which 5.0 mg of a 3-ketopentanenitrile, 50 mg of NADPH,
and 50 µl of 1 M phosphate buffer (pH 6.5) were
preliminarily placed was added 450 µl of the above cell-
free extract, followed by shaking overnight at 30°C.
Extraction was then performed twice using 1 ml of ethyl
acetate, followed by determining the production amount and
optical purity of the resultant 3-hydroxypentanenitrile.
As a result, the production amount was 2.5 mg, and the
optical purity was (R)98.4%e.e.

[0 1 1 9]

Example 16: Synthesis of a (R)-3-hydroxypentanenitrile
from a 3-ketopentanenitrile using the recombinant
Escherichia coli HB101 (pNTRE, pSTVG)

The recombinant *Escherichia coli* HB101 (pNTRE, pSTVG) was cultured as described in Example 7 to provide a culture solution. To 20 ml of the culture solution were added 5.0 g of glucose, 3 mg of $NADP^+$, and 0.2 g of a 3-ketopentanenitrile sodium salt, followed by stirring at 30°C while adding dropwise a 5N sodium hydroxide aqueous solution to adjust to pH 6.5. The addition of 0.2 g of the 3-ketopentanenitrile sodium salt was carried out 2, 3, 5, 7, 8, and 9 hours after the reaction. In addition, 4 ml of the culture solution and 3 mg of $NADP^+$ were added 10 hours after the reaction. The production amount and optical purity of the resultant 3-hydroxypentanenitrile were determined 24 hours after the reaction. As a result, the production amount was 1.0 g, and the optical purity was 98.3%e.e.

[0120]

Example 17: Synthesis of methyl (R)-3-hydroxybutanoate from methyl acetoacetate using the recombinant *Escherichia coli* HB101 (pNTAX, pSTVG)

The recombinant *Escherichia coli* HB101 (pNTAX, pSTVG) was cultured as described in Example 7. To 20 ml of the resultant culture solution were added 5.0 g of glucose, 3 mg of $NADP^+$, and 0.4 g of methyl acetoacetate, followed by stirring at 30°C while adding dropwise a 5N sodium hydroxide aqueous solution to adjust to pH 6.5. The addition of 0.4 g of methyl acetoacetate was carried out 1.5, 3, 4.5, 5.5, and 7 hours after the reaction. The

production amount of the resultant methyl 3-hydroxybutanoate was analyzed using capillary gas chromatography 24 hours after the reaction.

Analysis conditions

Column: TC-WAX (15 m × 0.25 mm) (from GL Science Inc.), Detection: FID, Column temperature: 85°C, Injection temperature: 200°C, Detection temperature: 200°C, Carrier gas: helium (70 kPa), Split ratio: 100/1, Elution time: 2.9 minutes for methyl acetoacetate, 3.8 minutes for methyl 3-hydroxybutanoate.

[0 1 2 1]

The methyl 3-hydroxybutanoate produced was dinitrobenzoylated before determining the optical purity thereof by HPLC analysis. The dinitrobenzoylation of methyl 3-hydroxybutanoate was carried out by extracting methyl 3-hydroxybutanoate with ethyl acetate from the reaction solution, and then adding 1.2 equivalents each of pyridine and 3,5-dinitrobenzoyl chloride based on the amount of methyl 3-hydroxybutanoate, followed by stirring at room temperature for 2 hours. After washing with 1N hydrochloride, purification was performed using thin layer chromatography for separation to provide the dinitrobenzoylated product of interest, which was then dissolved in ethanol and analyzed under the following HPLC analysis conditions.

Analysis conditions

Column: Chiralpak AD-H (from Daicel Chemical Industries, Ltd.), Detection wavelength: 230 nm, Column temperature: 20°C, Eluting solution: n-hexane/ethanol = 3/7, Flow rate: 0.7 ml/min., Elution time: 21.7 minutes for the S-form, 29.8 minutes for the R-form.

As a result, the production amount of methyl 3-hydroxybutanoate was 1.9 g, and the optical purity thereof was 97.2%e.e.

[0122]

Example 18: Synthesis of methyl (R)-3-hydroxybutanoate from methyl acetoacetate using the recombinant *Escherichia coli* HB101 (pNTRE, pSTVG)

A reaction was conducted as described in Example 17, except for use of the recombinant *Escherichia coli* HB101 (pNTRE, pSTVG) in place of the recombinant *Escherichia coli* HB101 (pNTAX, pSTVG), and, 24 hours after the reaction, the production amount and optical purity of the resultant methyl 3-hydroxybutanoate were determined. As a result, the production amount of methyl 3-hydroxybutanoate was 1.9 g, and the optical purity thereof was 98.3%e.e.

[0123]

Example 19: Synthesis of (R)-2-chloro-1-(3'-chlorophenyl)ethanol from 2-chloro-1-(3'-chlorophenyl)ethanone using the recombinant *Escherichia coli* HB101 (pNTAX, pSTVG)

The recombinant *Escherichia coli* HB101 (pNTAX, pSTVG) was cultured as described in Example 7. To 20 ml of the resultant culture solution were added 5.0 g of glucose, 3 mg of NADP$^+$, and 0.4 g of 2-chloro-1-(3'-chlorophenyl)ethanone, followed by stirring at 30°C while adding dropwise a 5N sodium hydroxide aqueous solution to adjust to pH 6.5. The addition of 0.4 g of 2-chloro-1-(3'-chlorophenyl)ethanone was carried out 2, 4, 6, and 8 hours after the reaction. The production amount of the resultant 2-chloro-1-(3'-chlorophenyl)ethanol and the optical purity thereof were determined by analysis under the following conditions 24 hours after the reaction.

[0 1 2 4]

Analysis conditions

Column: Chiralpak OJ (from Daicel Chemical Industries, Ltd.), Detection wavelength: 210 nm, Column temperature: 20°C, Eluting solution: n-hexane/isopropanol = 39/1, Flow rate: 1.0 ml/min., Elution time: 25.3 minutes for 2-chloro-1-(3'-chlorophenyl)ethanone, 38.4 minutes for (R)-2-chloro-1-(3'-chlorophenyl)ethanol, 44.0 minutes for (S)-2-chloro-1-(3'-chlorophenyl)ethanol

As a result, the production amount of 2-chloro-1-(3'-chlorophenyl)ethanol was 1.9 g, and the optical purity thereof was 99.0%e.e.

【0125】

Example 20: Synthesis of (R)-2-chloro-1-(3'-chlorophenyl)ethanol from 2-chloro-1-(3'-chlorophenyl)ethanone using the recombinant *Escherichia coli* HB101 (pNTRE, pSTVG)

A reaction was conducted as described in Example 19, except for use of the recombinant *Escherichia coli* HB101 (pNTRE, pSTVG) in place of the recombinant *Escherichia coli* HB101 (pNTAX, pSTVG), and, 24 hours after the reaction, the production amount and optical purity of the resultant 2-chloro-1-(3'-chlorophenyl)ethanol were determined. As a result, the production amount of 2-chloro-1-(3'-chlorophenyl)ethanol was 1.9 g, and the optical purity thereof was 99.9%e.e.

Industrial Applicability

【0126】

According to the invention, useful optically active alcohols such as a (R)-3-hydroxypentanenitrile, (R)-3-hydroxybutanoic esters, and optically active 1-phenylethanol derivatives may be produced in a simple and easy manner. Particularly for a (R)-3-hydroxypentanenitrile, non-conventional products having extremely high optical purities of 95%e.e. or more and, when the acetoacetyl-CoA reductase of the invention is used, 99%e.e. or more can be obtained.
